Rust is a plant disease caused by various fungi that typically manifest as reddish-brown or orange powdery spots on the leaves, stems, or other plant parts. These fungal infections weaken the plant by disrupting its ability to photosynthesize and absorb nutrients. Rust diseases are often specific to certain plant species and can lead to reduced crop yields and overall plant health. Prevention involves practices such as crop rotation, selecting resistant plant varieties, and applying fungicides when necessary. Timely identification and management of rust diseases are crucial for maintaining the vitality of plants and preventing the spread of infections within a crop or garden.
